# Error-correcting codes (recall)

---

- Primary use case: communication over a noisy channel.
- Main idea: introduce some **redundancy** in order to be able to correct the errors.
- Some structured error-correcting codes have efficient decoding algorithms.
- Decoding is, in general, a **hard problem** - so it is hard for *random* codes.

↪ Hard problems (often) find their use in cryptography.

# Linear codes (recall)

---

## Linear code

An  $[n, k]$  **linear code**  $\mathcal{C}$  over  $\mathbb{F}_q$  is a  $k$ -dimensional subspace of  $\mathbb{F}_q^n$ .

- The parameter  $n$  is called the **length** of the code.
- The parameter  $k$  is called the **dimension** of the code.
- The elements in the code are called **codewords**.

## Hamming metric

For  $\mathbf{x} \in \mathbb{F}_q^n$  the **Hamming weight** of  $\mathbf{x}$  is the number of nonzero elements, aka.

$$\text{wt}(\mathbf{x}) = |\{i \in \{1, \dots, n\} \mid x_i \neq 0\}|.$$

## Generator matrix

The matrix  $\mathbf{G} \in \mathbb{F}_q^{k \times n}$  is called a **generator matrix** of  $\mathcal{C}$ , if

$$\mathcal{C} = \{\mathbf{xG} \mid \mathbf{x} \in \mathbb{F}_q^k\}.$$

# Binary linear codes

---

## Binary linear code

An  $[n, k]$  **binary linear code**  $\mathcal{C}$  is a  $k$ -dimensional subspace of  $\mathbb{F}_2^n$ .

- The parameter  $n$  is called the **length** of the code.
- The parameter  $k$  is called the **dimension** of the code.
- The elements in the code are called **codewords**.

## Hamming metric

For  $\mathbf{x} \in \mathbb{F}_2^n$ , the **Hamming weight** of  $\mathbf{x}$  is the number of nonzero elements, aka.

$$\text{wt}(\mathbf{x}) = |\{i \in \{1, \dots, n\} \mid x_i \neq 0\}|.$$

## Generator matrix

The matrix  $\mathbf{G} \in \mathbb{F}_2^{k \times n}$  is called a **generator matrix** of  $\mathcal{C}$ , if

$$\mathcal{C} = \{\mathbf{xG} \mid \mathbf{x} \in \mathbb{F}_2^k\}.$$

# Binary linear codes

---

## Binary linear code

An  $[n, k]$  **binary linear code**  $\mathcal{C}$  is a  $k$ -dimensional subspace of  $\mathbb{F}_2^n$ .

**Example.**  $q = 2, n = 5, k = 3$

$$\mathbf{G} = \begin{pmatrix} 1 & 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 0 & 0 \\ 1 & 1 & 1 & 1 & 0 \end{pmatrix}$$

Codewords:  $\lambda_1(10101) + \lambda_2(11000) + \lambda_3(11110)$

**Example.**  $\mathbf{c}_1 = (111)\mathbf{G} = (10011)$ ,  
 $\mathbf{c}_2 = (100)\mathbf{G} = (10101)$

# Decoding

---

→ Encoding:  $\mathbf{c} = \mathbf{mG}$

→ Introducing error  $\mathbf{e}$  of low weight:  $\mathbf{y} = \mathbf{c} + \mathbf{e} = \mathbf{mG} + \mathbf{e}$ , s.t.  $\text{wt}(\mathbf{e}) = t$ .

→ Decoding: Given  $\mathbf{y}$ , find  $\mathbf{c}$  s.t.  $\mathbf{y} = \mathbf{c} + \mathbf{e}$  and  $\text{wt}(\mathbf{e}) \leq t$ .

# Representations of linear codes

---

→ The row space of a **generator matrix**  $\mathbf{G} \in \mathbb{F}_2^{k \times n}$ :

$$\mathcal{C} = \{\mathbf{xG} \mid \mathbf{x} \in \mathbb{F}_2^k\}.$$

→ The kernel space of a **parity-check matrix**  $\mathbf{H} \in \mathbb{F}_2^{(n-k) \times n}$ :

$$\mathcal{C} = \{\mathbf{c} \mid \mathbf{Hc} = 0, \mathbf{c} \in \mathbb{F}_2^n\}.$$

**Example.**  $n = 7, k = 4$

$$\mathbf{G} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{pmatrix}$$

**Example.**  $n = 7, k = 4$

$$\mathbf{H} = \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix}$$

\*We are omitting the transpose (T) for vectors.

# From $\mathbf{G}$ to $\mathbf{H}$

## Systematic form

A systematic generator matrix is a generator matrix of the form

$(\mathbf{I}_k | \mathbf{Q})$ , where  $\mathbf{I}_k$  is the  $k \times k$  identity matrix and  $\mathbf{Q}$  is a  $k \times (n - k)$  matrix.

information part

redundant part

**Example.**  $\mathbf{G} \rightarrow \tilde{\mathbf{G}}$

$$\mathbf{G} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{pmatrix} \longrightarrow \tilde{\mathbf{G}} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{pmatrix}$$

→ When  $\mathbf{c} = \mathbf{m}\tilde{\mathbf{G}}$ , the first  $k$  positions of  $\mathbf{c}$  are  $\mathbf{m}$ .

**Example.**  $(1010)\tilde{\mathbf{G}} = (1010101)$

# From $\mathbf{G}$ to $\mathbf{H}$

## Systematic form

A systematic generator matrix is a generator matrix of the form

$(\mathbf{I}_k | \mathbf{Q})$ , where  $\mathbf{I}_k$  is the  $k \times k$  identity matrix and  $\mathbf{Q}$  is a  $k \times (n - k)$  matrix.

information part

redundant part

Example.  $\mathbf{G} \rightarrow \tilde{\mathbf{G}}$

$$\mathbf{G} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 1 & 1 & 0 & 1 & 1 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \end{pmatrix} \longrightarrow \tilde{\mathbf{G}} = \begin{pmatrix} 1 & 0 & 0 & 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 & 1 & 1 & 1 \end{pmatrix}$$

→ We can form the parity-check matrix as  $\mathbf{H} = (\mathbf{Q}^T | \mathbf{I}_{n-k})$ .

Example.

$$\mathbf{H} = \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix}$$

# From $\mathbf{G}$ to $\mathbf{H}$

---

→ We have  $\tilde{\mathbf{G}} = (\mathbf{I}_k | \mathbf{Q})$ .

→ We can form the parity-check matrix as  $\mathbf{H} = (\mathbf{Q}^\top | \mathbf{I}_{n-k})$ .

↪ Every codeword is in the kernel space of  $\mathbf{H}$ :

$$\mathbf{H}(\mathbf{m}\tilde{\mathbf{G}})^\top = \mathbf{H}\tilde{\mathbf{G}}^\top \mathbf{m}^\top = (\mathbf{Q}^\top \quad \mathbf{I}_{n-k}) \begin{pmatrix} \mathbf{I}_k \\ \mathbf{Q}^\top \end{pmatrix} \mathbf{m}^\top = (\mathbf{Q}^\top + \mathbf{Q}^\top) \mathbf{m}^\top = \mathbf{0} \cdot \mathbf{m}^\top = \mathbf{0}$$

# Example: Hamming code

---

Columns correspond to a bit pattern of length  $(n - k)$ .

**Example.**  $n = 7, k = 4$

$$\mathbf{H} = \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix}$$

# Example: Hamming code

---

 Columns correspond to a bit pattern of length  $(n - k)$ .

**Example.**  $n = 7, k = 4$

$$\begin{array}{c} \mathbf{H} \\ \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix} \end{array} \quad \begin{array}{c} \mathbf{c} \\ \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \\ 1 \\ 0 \\ 1 \end{pmatrix} \end{array} = \begin{pmatrix} 0 \\ 0 \\ 0 \end{pmatrix}$$

# Example: Hamming code

---

An error occurs.

**Example.**  $n = 7, k = 4$

$$\begin{array}{c} \mathbf{H} \\ \left( \begin{array}{cccccc} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{array} \right) \end{array} \left( \begin{array}{c} \mathbf{c} \\ 1 \\ 0 \\ 1 \\ 0 \\ 1 \\ 0 \\ 1 \end{array} \right) + \left( \begin{array}{c} \mathbf{e} \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array} \right) = \left( \begin{array}{c} 1 \\ 1 \\ 0 \end{array} \right)$$

# Example: Hamming code

---

An error occurs.

**Example.**  $n = 7, k = 4$

$$\begin{array}{c} \mathbf{H} \\ \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix} \end{array} \begin{array}{c} \mathbf{c} \\ \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \\ 1 \\ 0 \\ 1 \end{pmatrix} \end{array} + \begin{array}{c} \mathbf{e} \\ \begin{pmatrix} 0 \\ 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{pmatrix} \end{array} = \begin{array}{c} \begin{pmatrix} 1 \\ 0 \\ 1 \end{pmatrix} \end{array}$$

# Example: Hamming code

An error occurs.

**Example.**  $n = 7, k = 4$

$$\mathbf{H} \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} 1 \\ 0 \\ 1 \\ 0 \\ 1 \\ 0 \\ 1 \end{pmatrix} + \begin{pmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}$$

The **failure pattern** uniquely identifies the error location.

We will call it a **syndrome**.

# Syndrome decoding

---

## Syndrome

The **syndrome** of a word  $\mathbf{y} \in \mathbb{F}_2^n$  is  $\mathbf{s} = \mathbf{H}\mathbf{y}$ .

$$\mathbf{H}\mathbf{y} = \mathbf{H}(\mathbf{c} + \mathbf{e}) = \mathbf{H}\mathbf{c} + \mathbf{H}\mathbf{e} = \mathbf{0} + \mathbf{H}\mathbf{e} = \mathbf{H}\mathbf{e}$$

The syndrome depends only on the error vector.

# The syndrome decoding problem

---

## The syndrome decoding problem

Given a syndrome  $\mathbf{s} = \mathbf{H}\mathbf{e}$ , find  $\mathbf{e}$  such that  $\text{wt}(\mathbf{e}) \leq t$ .

$$\begin{matrix} & \mathbf{H} & & \mathbf{e} & = & \mathbf{s} \\ \begin{pmatrix} 1 & 1 & 0 & 1 & 1 & 0 & 0 \\ 1 & 0 & 1 & 1 & 0 & 1 & 0 \\ 0 & 1 & 1 & 1 & 0 & 0 & 1 \end{pmatrix} & & \begin{pmatrix} e_1 \\ e_2 \\ e_3 \\ e_4 \\ e_5 \\ e_6 \\ e_7 \end{pmatrix} & & & \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix} \end{matrix}$$

 Find  $\mathbf{e}$  of minimum weight.

# Information set decoding

# Information set decoding algorithms

---

Focus on the case  $\text{wt}(\mathbf{e}) = t$ .

## The syndrome decoding problem

Given a syndrome  $\mathbf{s} = \mathbf{H}\mathbf{e}$ , find  $\mathbf{e}$  such that  $\text{wt}(\mathbf{e}) = t$ .

# Brute force

---

□ Entry is 0

■ Entry is 1

■ Entry is 0 or 1

↪ **s** is equal to the sum of the columns where  $e_i$  is nonzero.

→ Pick any group of  $t$  columns of **H**, add them and compare with **s**.

# Brute force: complexity

---

=

→ Pick any group of  $t$  columns of  $\mathbf{H}$ , add them and compare with  $\mathbf{s}$ .

↪ Cost:  $\binom{n}{t}$  sums of  $t$  columns.

# Prange's attack

---

→ Permute **H** and bring to systematic form.

# Prange's attack

---

$$\mathbf{H}' = \mathbf{UHP}$$

$\mathbf{e}$

$$\mathbf{s}' = \mathbf{Us}$$

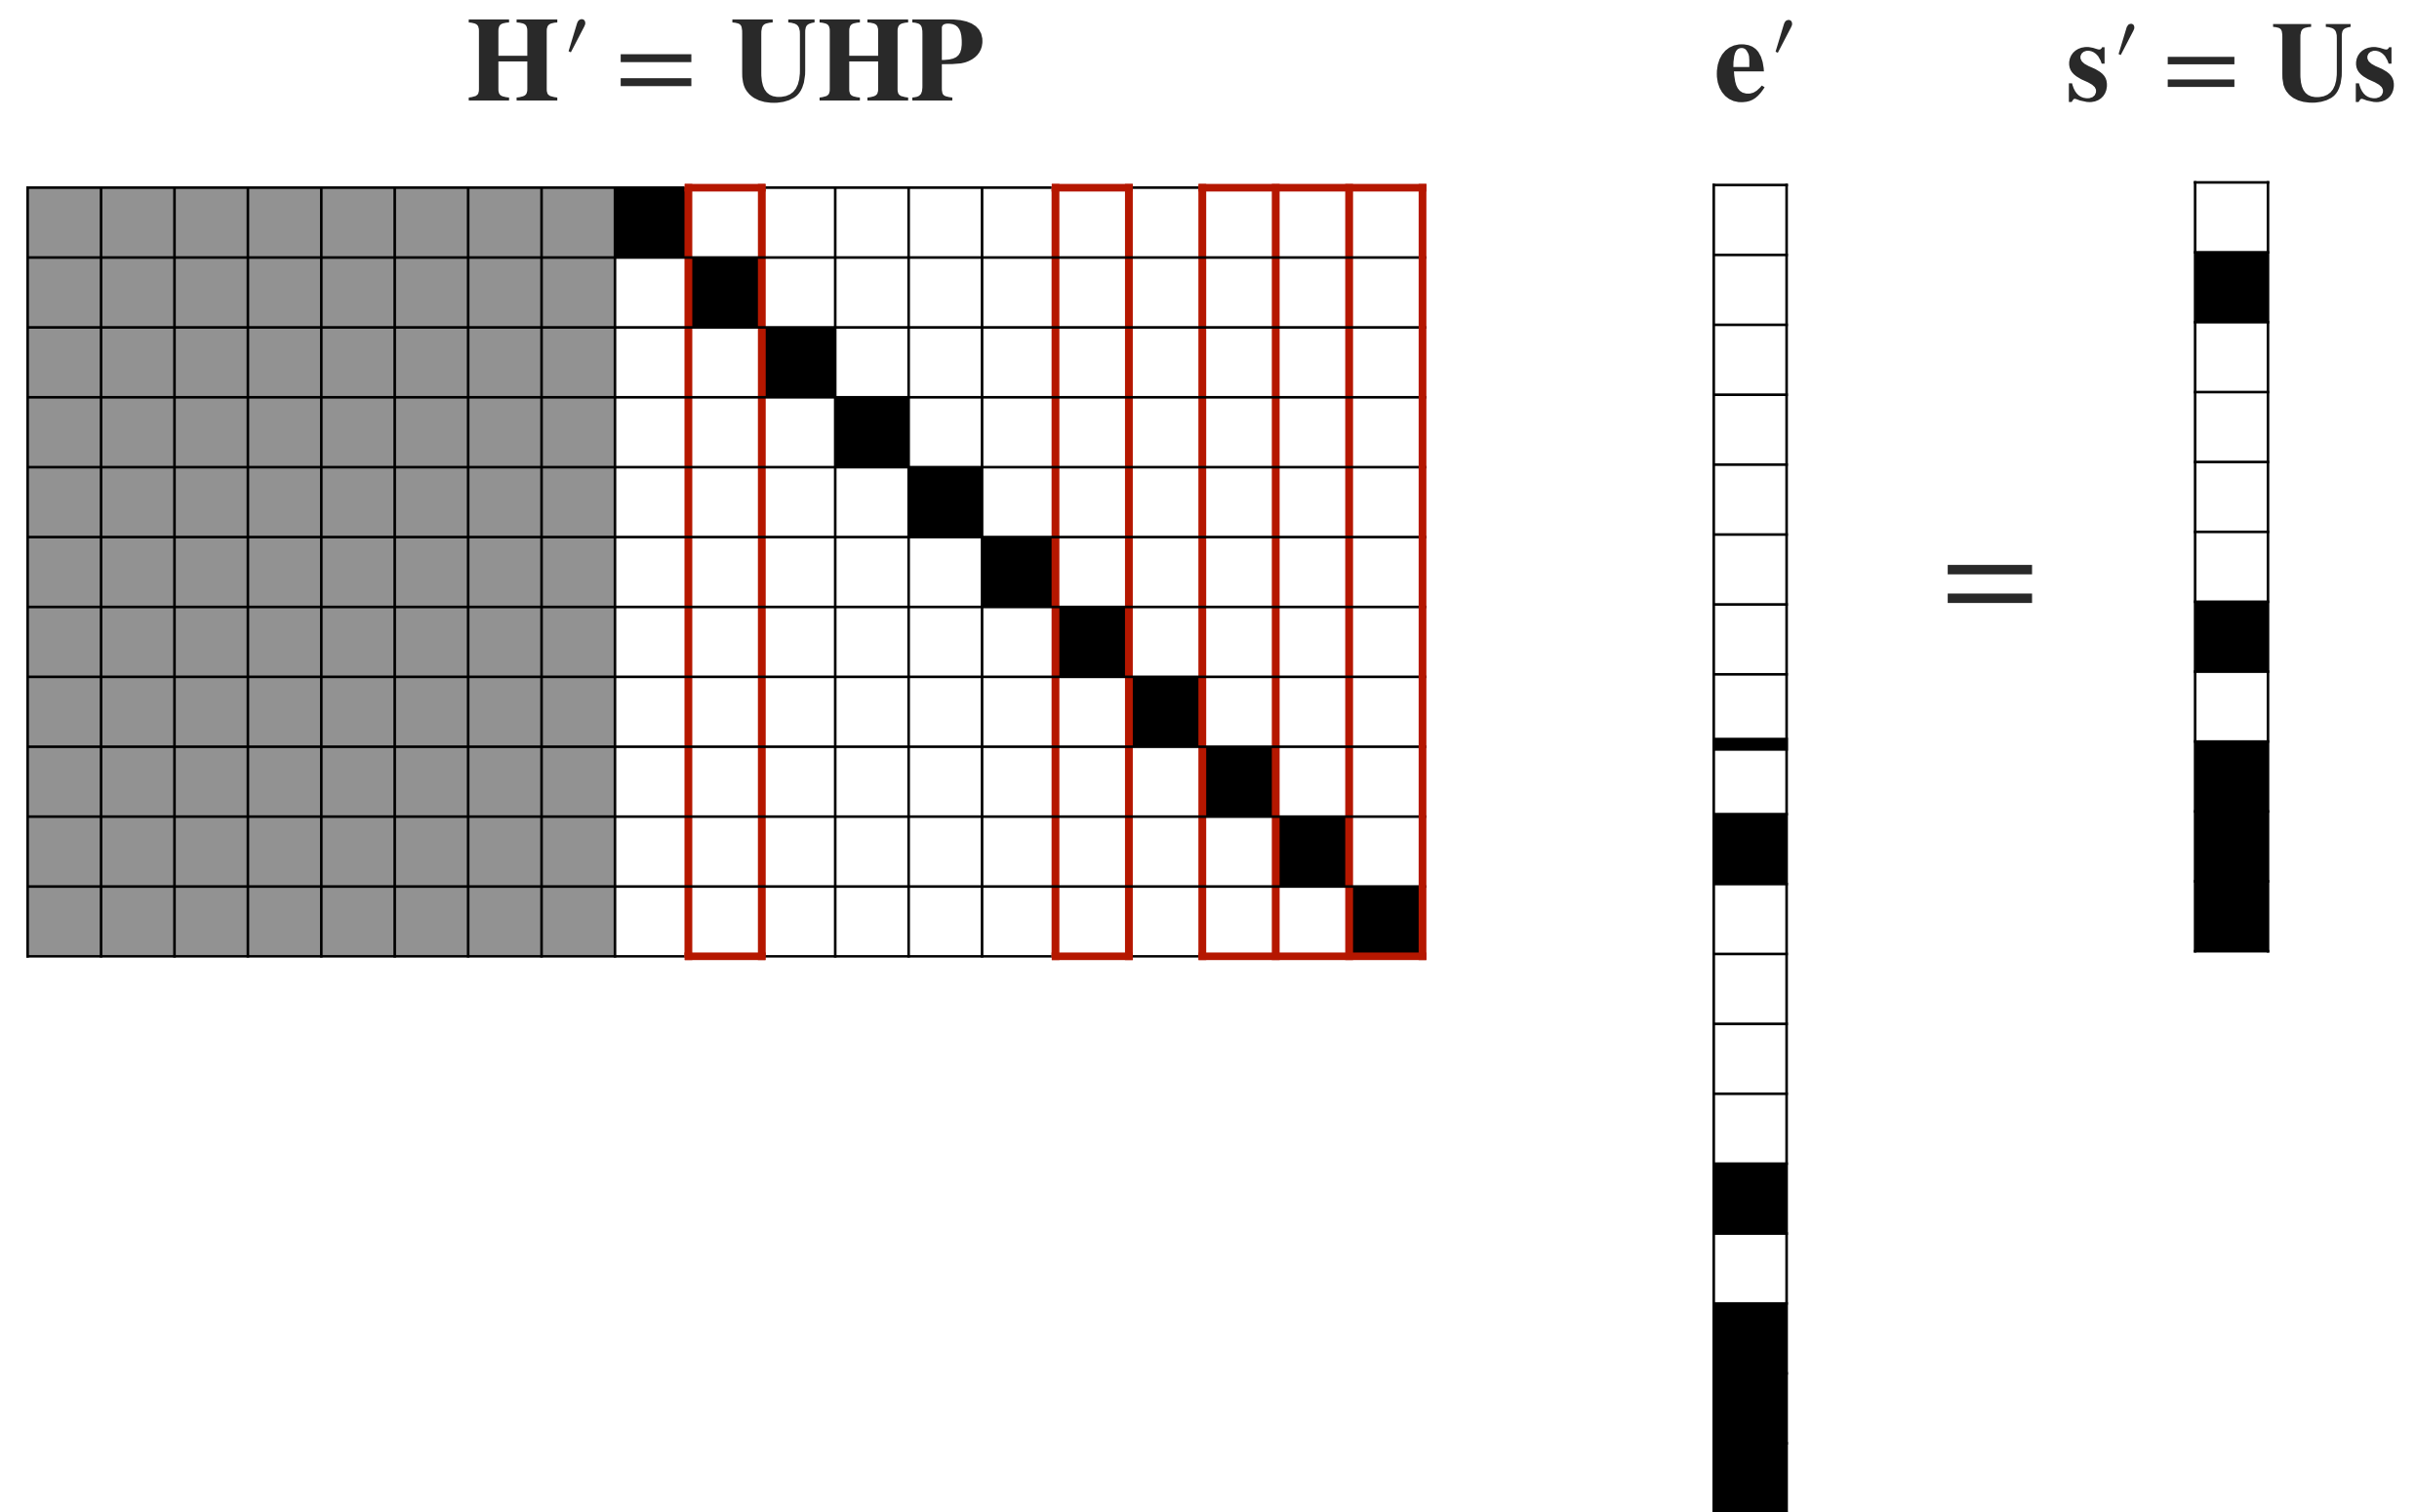

$=$

→ Permute  $\mathbf{H}$  and bring to systematic form.

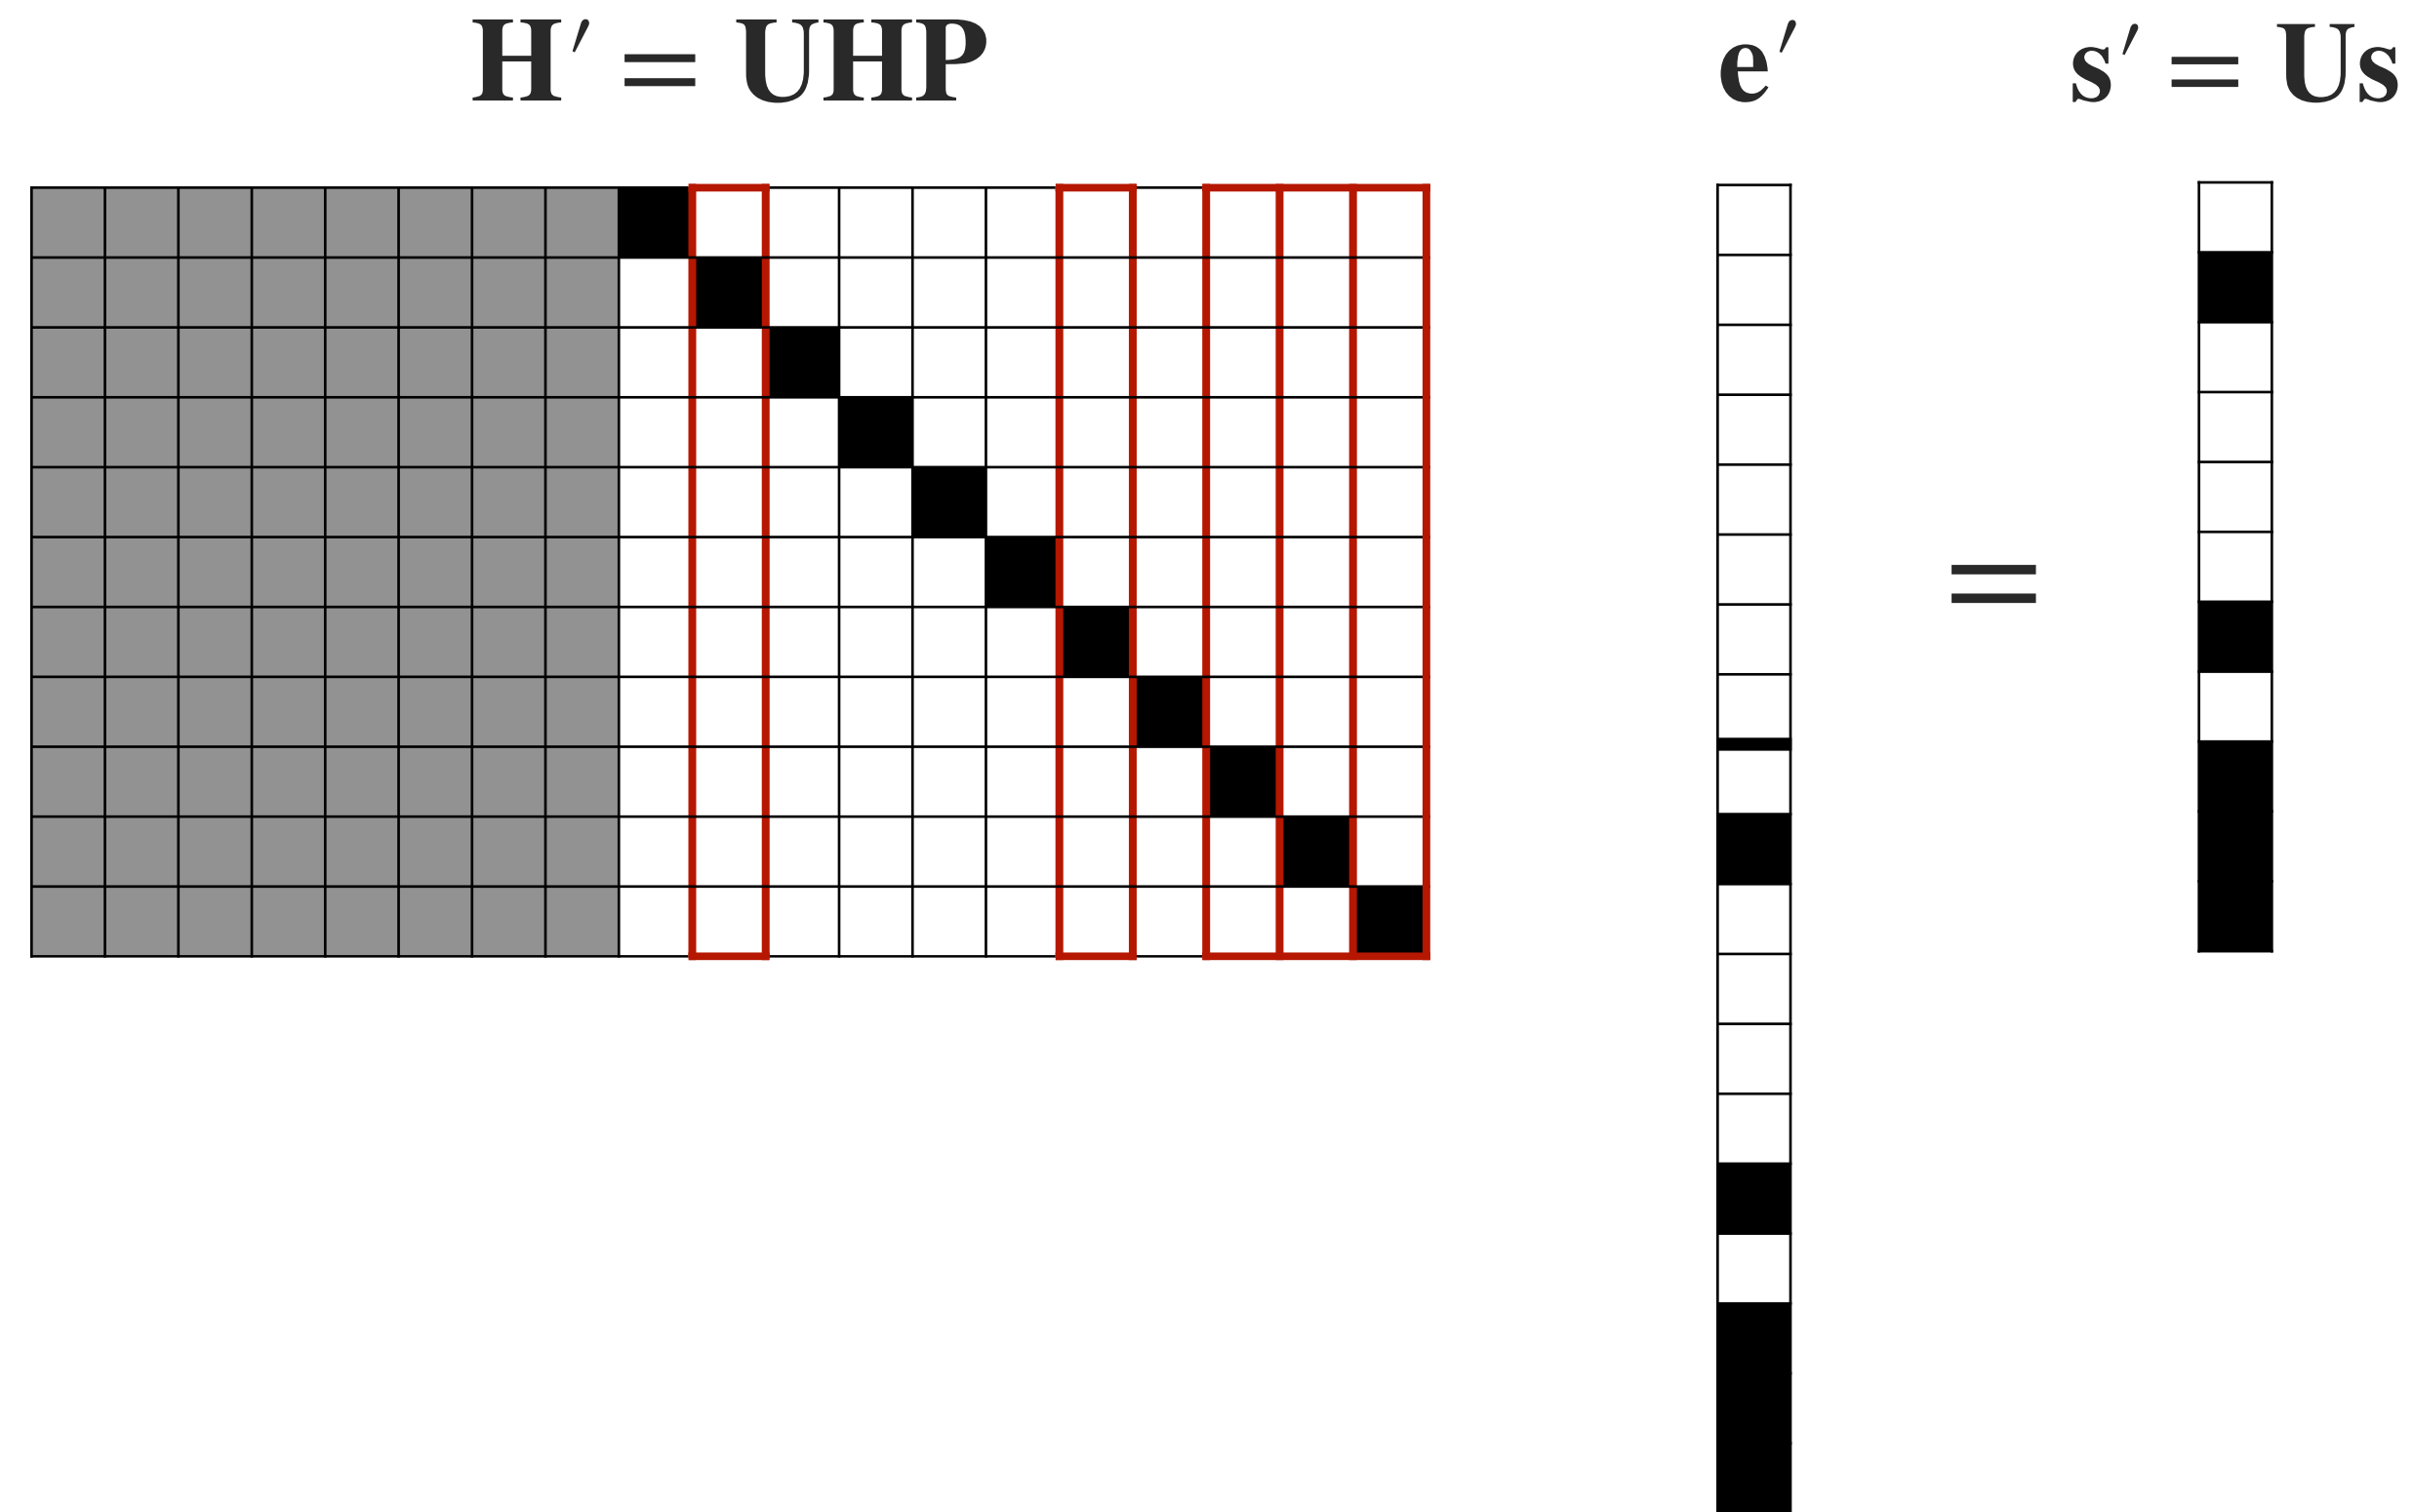

# Prange's attack

→ Permute  $\mathbf{H}$  and bring to systematic form.

Suppose that all  $t$  errors are in the identity (right) part. Then  $\mathbf{e}' = (000\dots) \parallel \mathbf{Us}$  and  $\text{wt}(\mathbf{Us}) = t$ .

# Prange's attack

- Permute  $\mathbf{H}$  and bring to systematic form.  
Suppose that all  $t$  errors are in the identity (right) part. Then  $\mathbf{e}' = (000\dots) || \mathbf{Us}$  and  $\text{wt}(\mathbf{Us}) = t$ .
- If  $\text{wt}(\mathbf{Us}) = t$ , then output unpermuted version of  $\mathbf{e}'$ .
- Else, return to the first step and rerandomize: choose a new permutation.

# Prange's attack: complexity

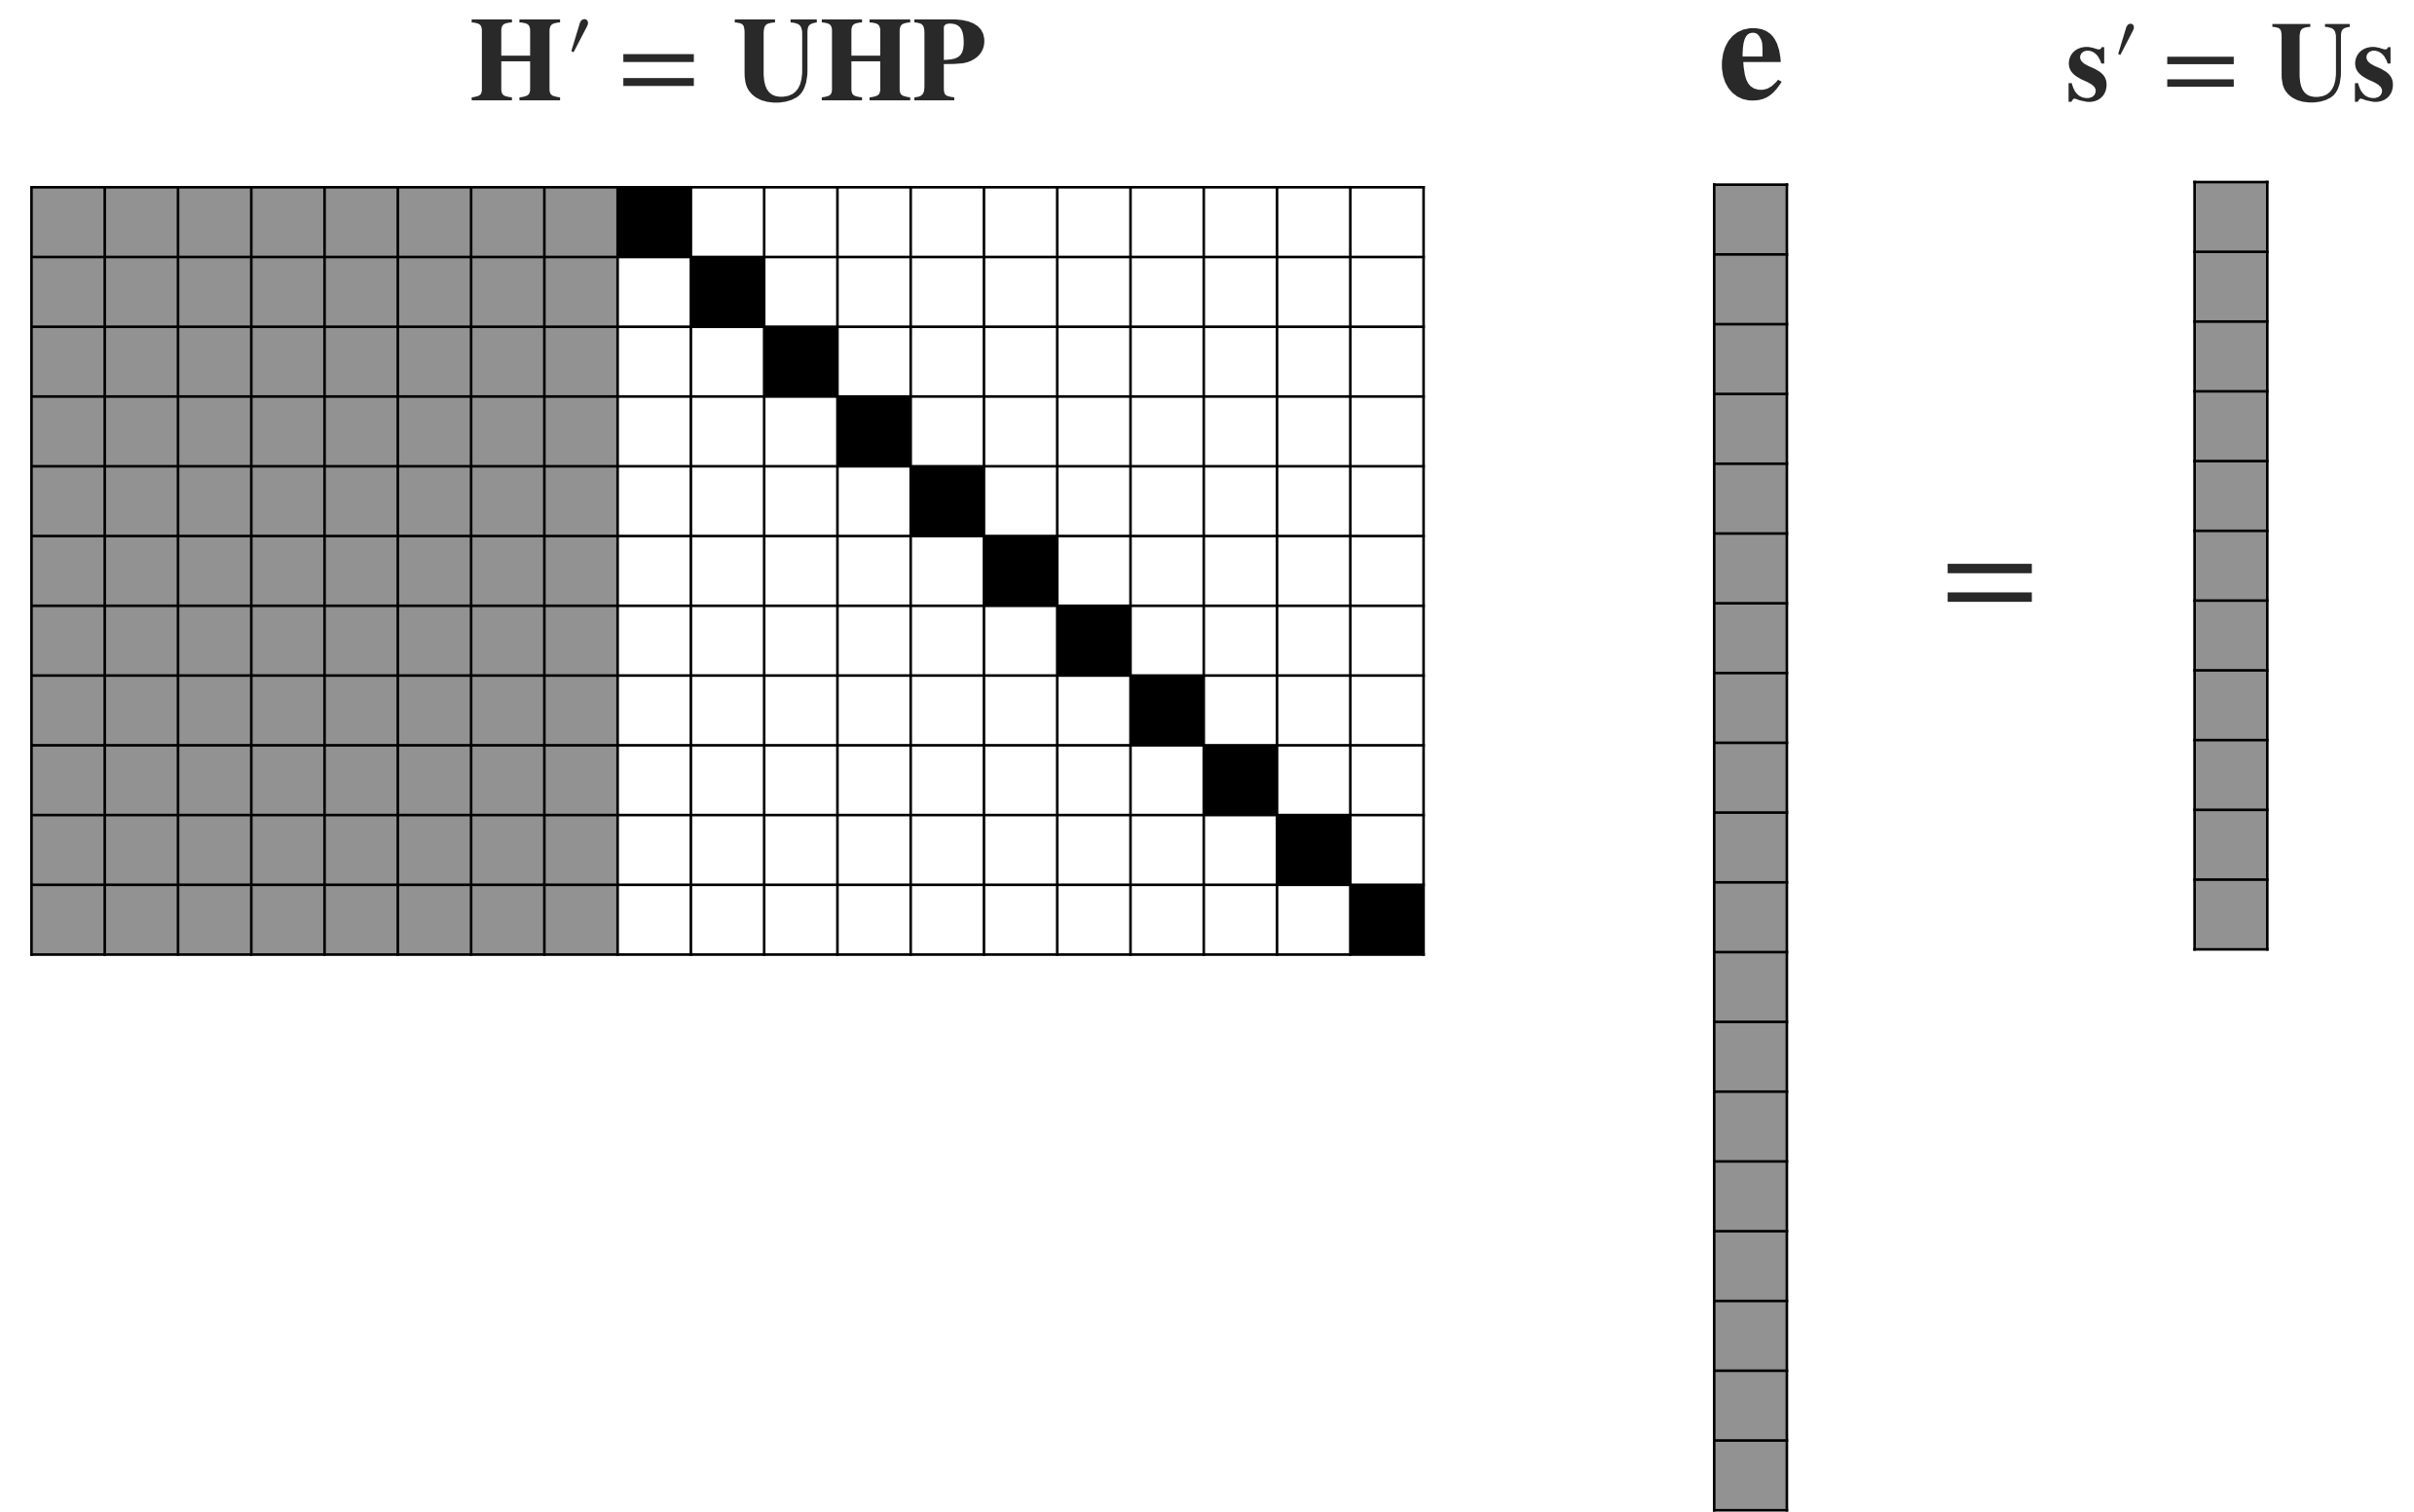

- Permute  $\mathbf{H}$  and bring to systematic form.
- If  $\text{wt}(\mathbf{U}\mathbf{s}) = t$ , then output unpermuted version of  $\mathbf{e}$ .
- Else, return to the first step and rerandomize: choose a new permutation.

All errors are in the identity part

Probability that we are in the correct configuration:  $\frac{\binom{n-k}{t}}{\binom{n}{t}}$ .

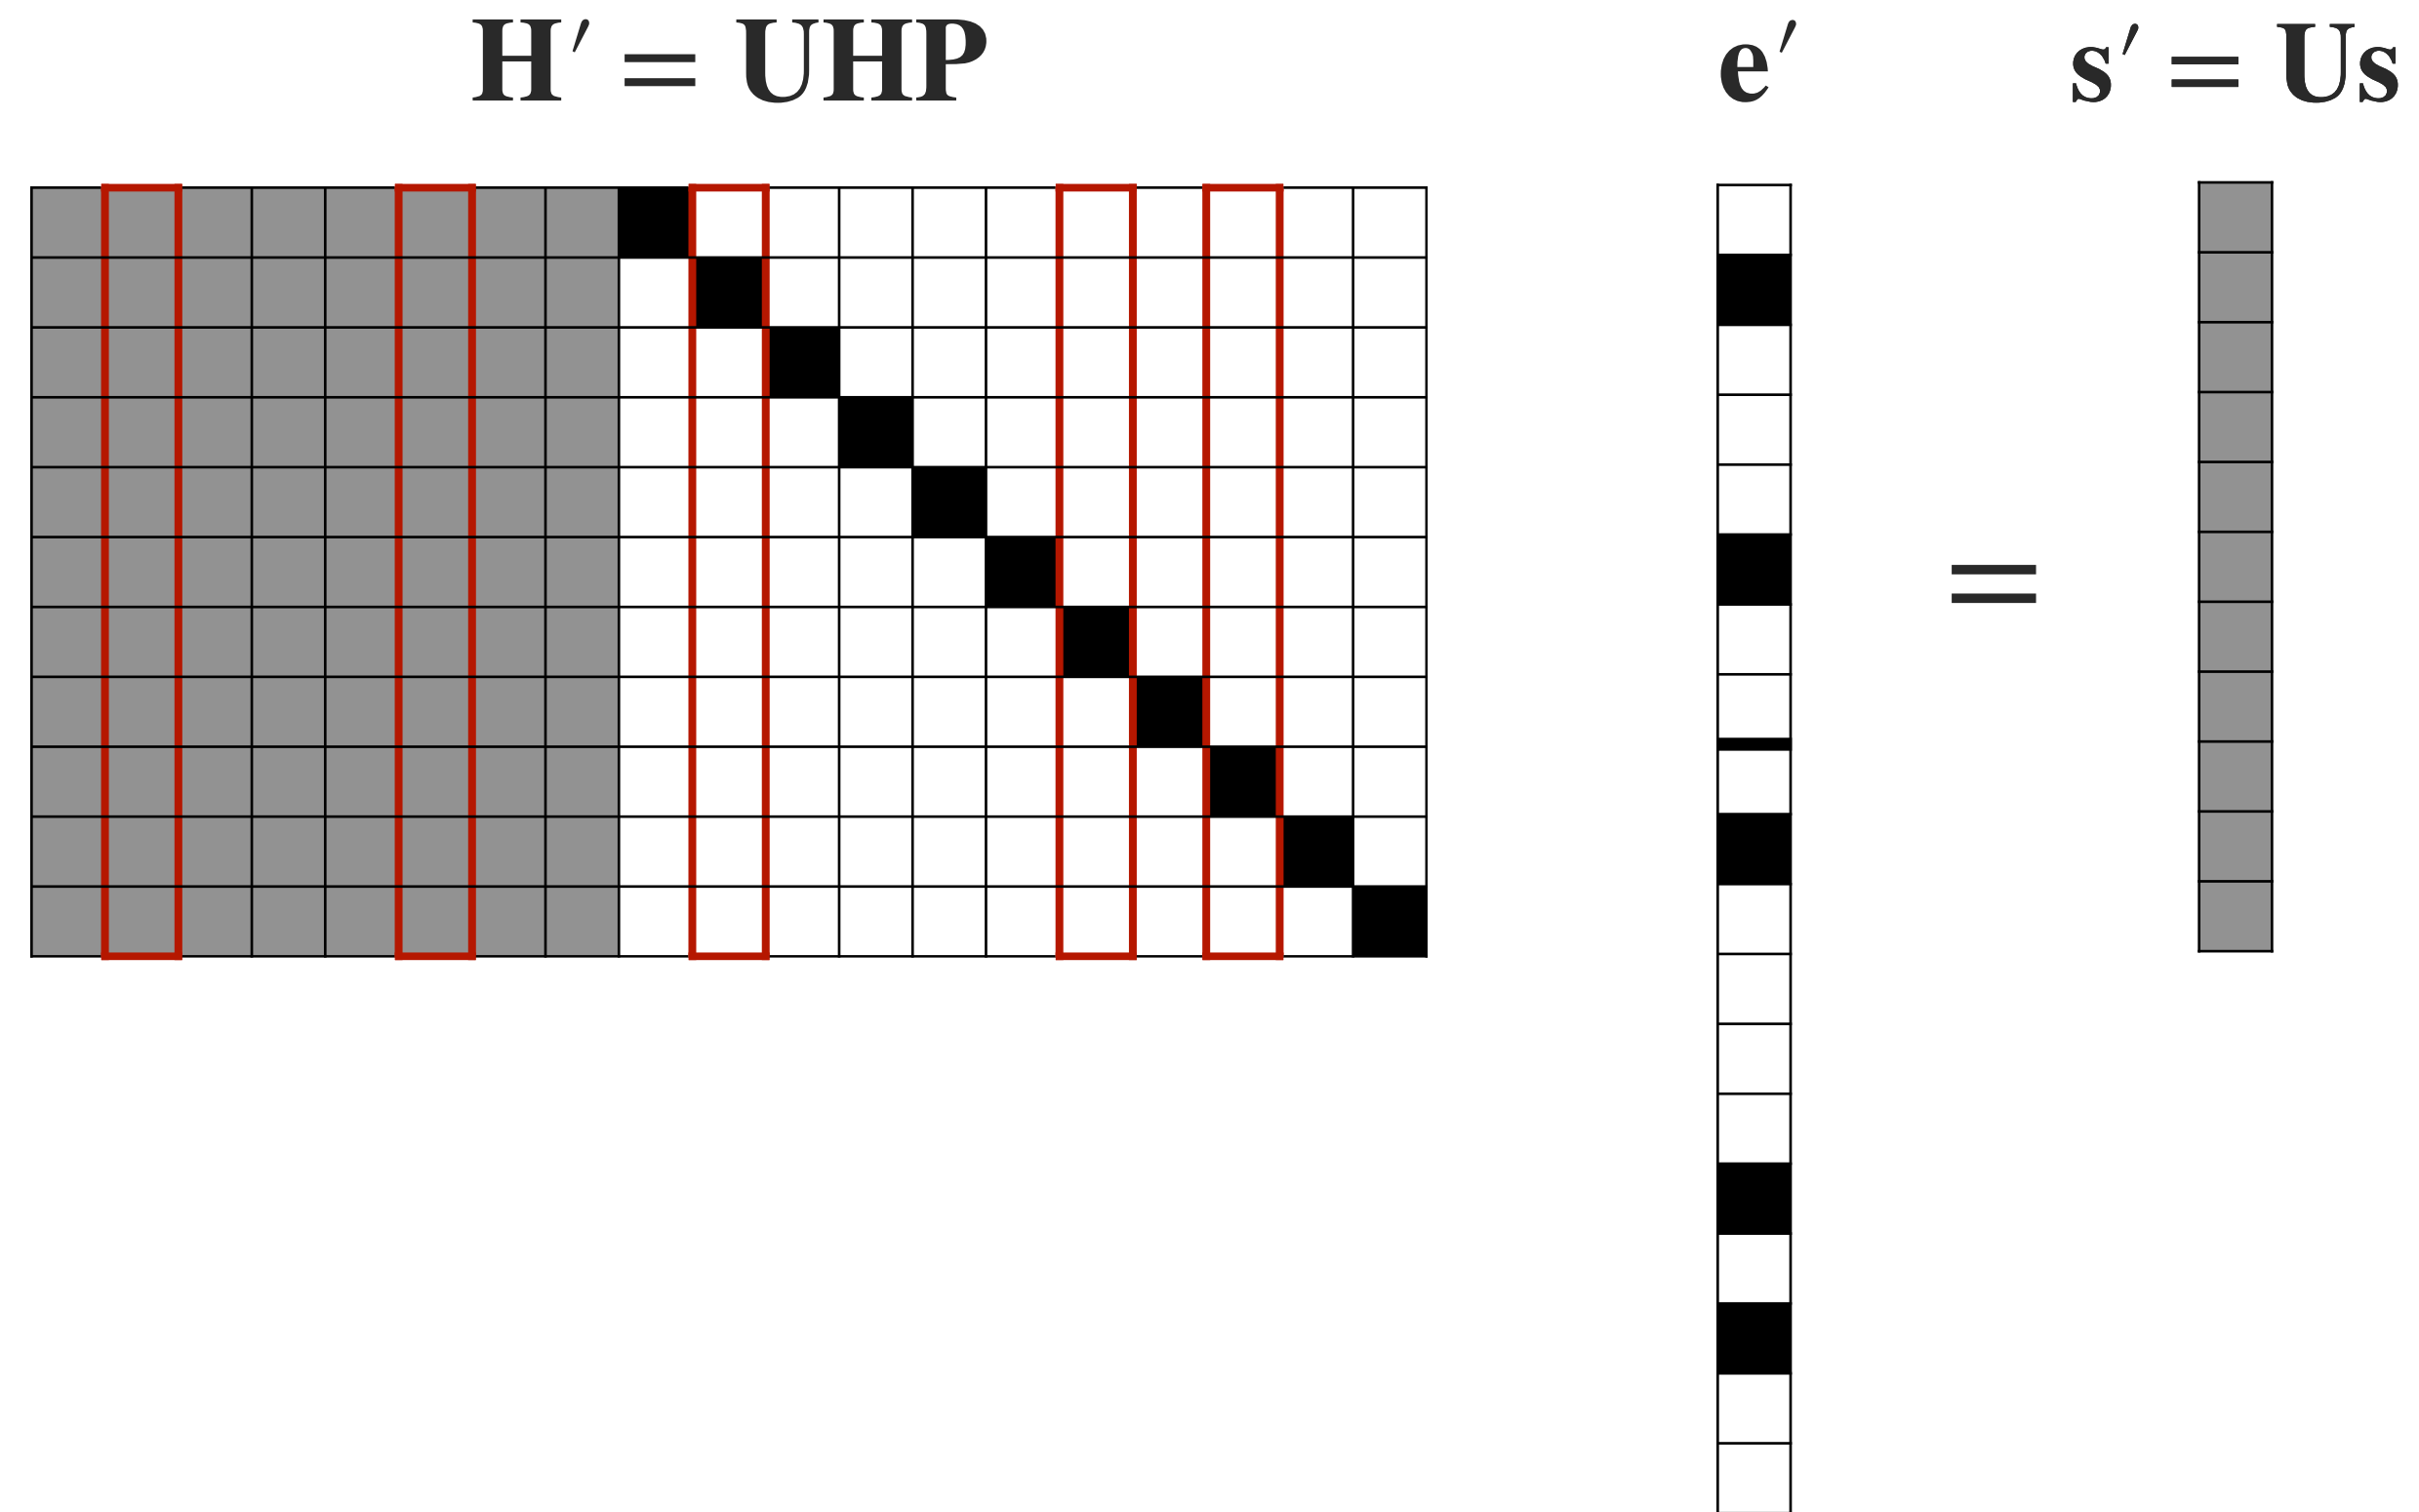

Cost:  $\frac{\binom{n}{t}}{\binom{n-k}{t}}$  matrix operations.

# Lee-Brickell attack

→ Permute  $\mathbf{H}$  and bring to systematic form.

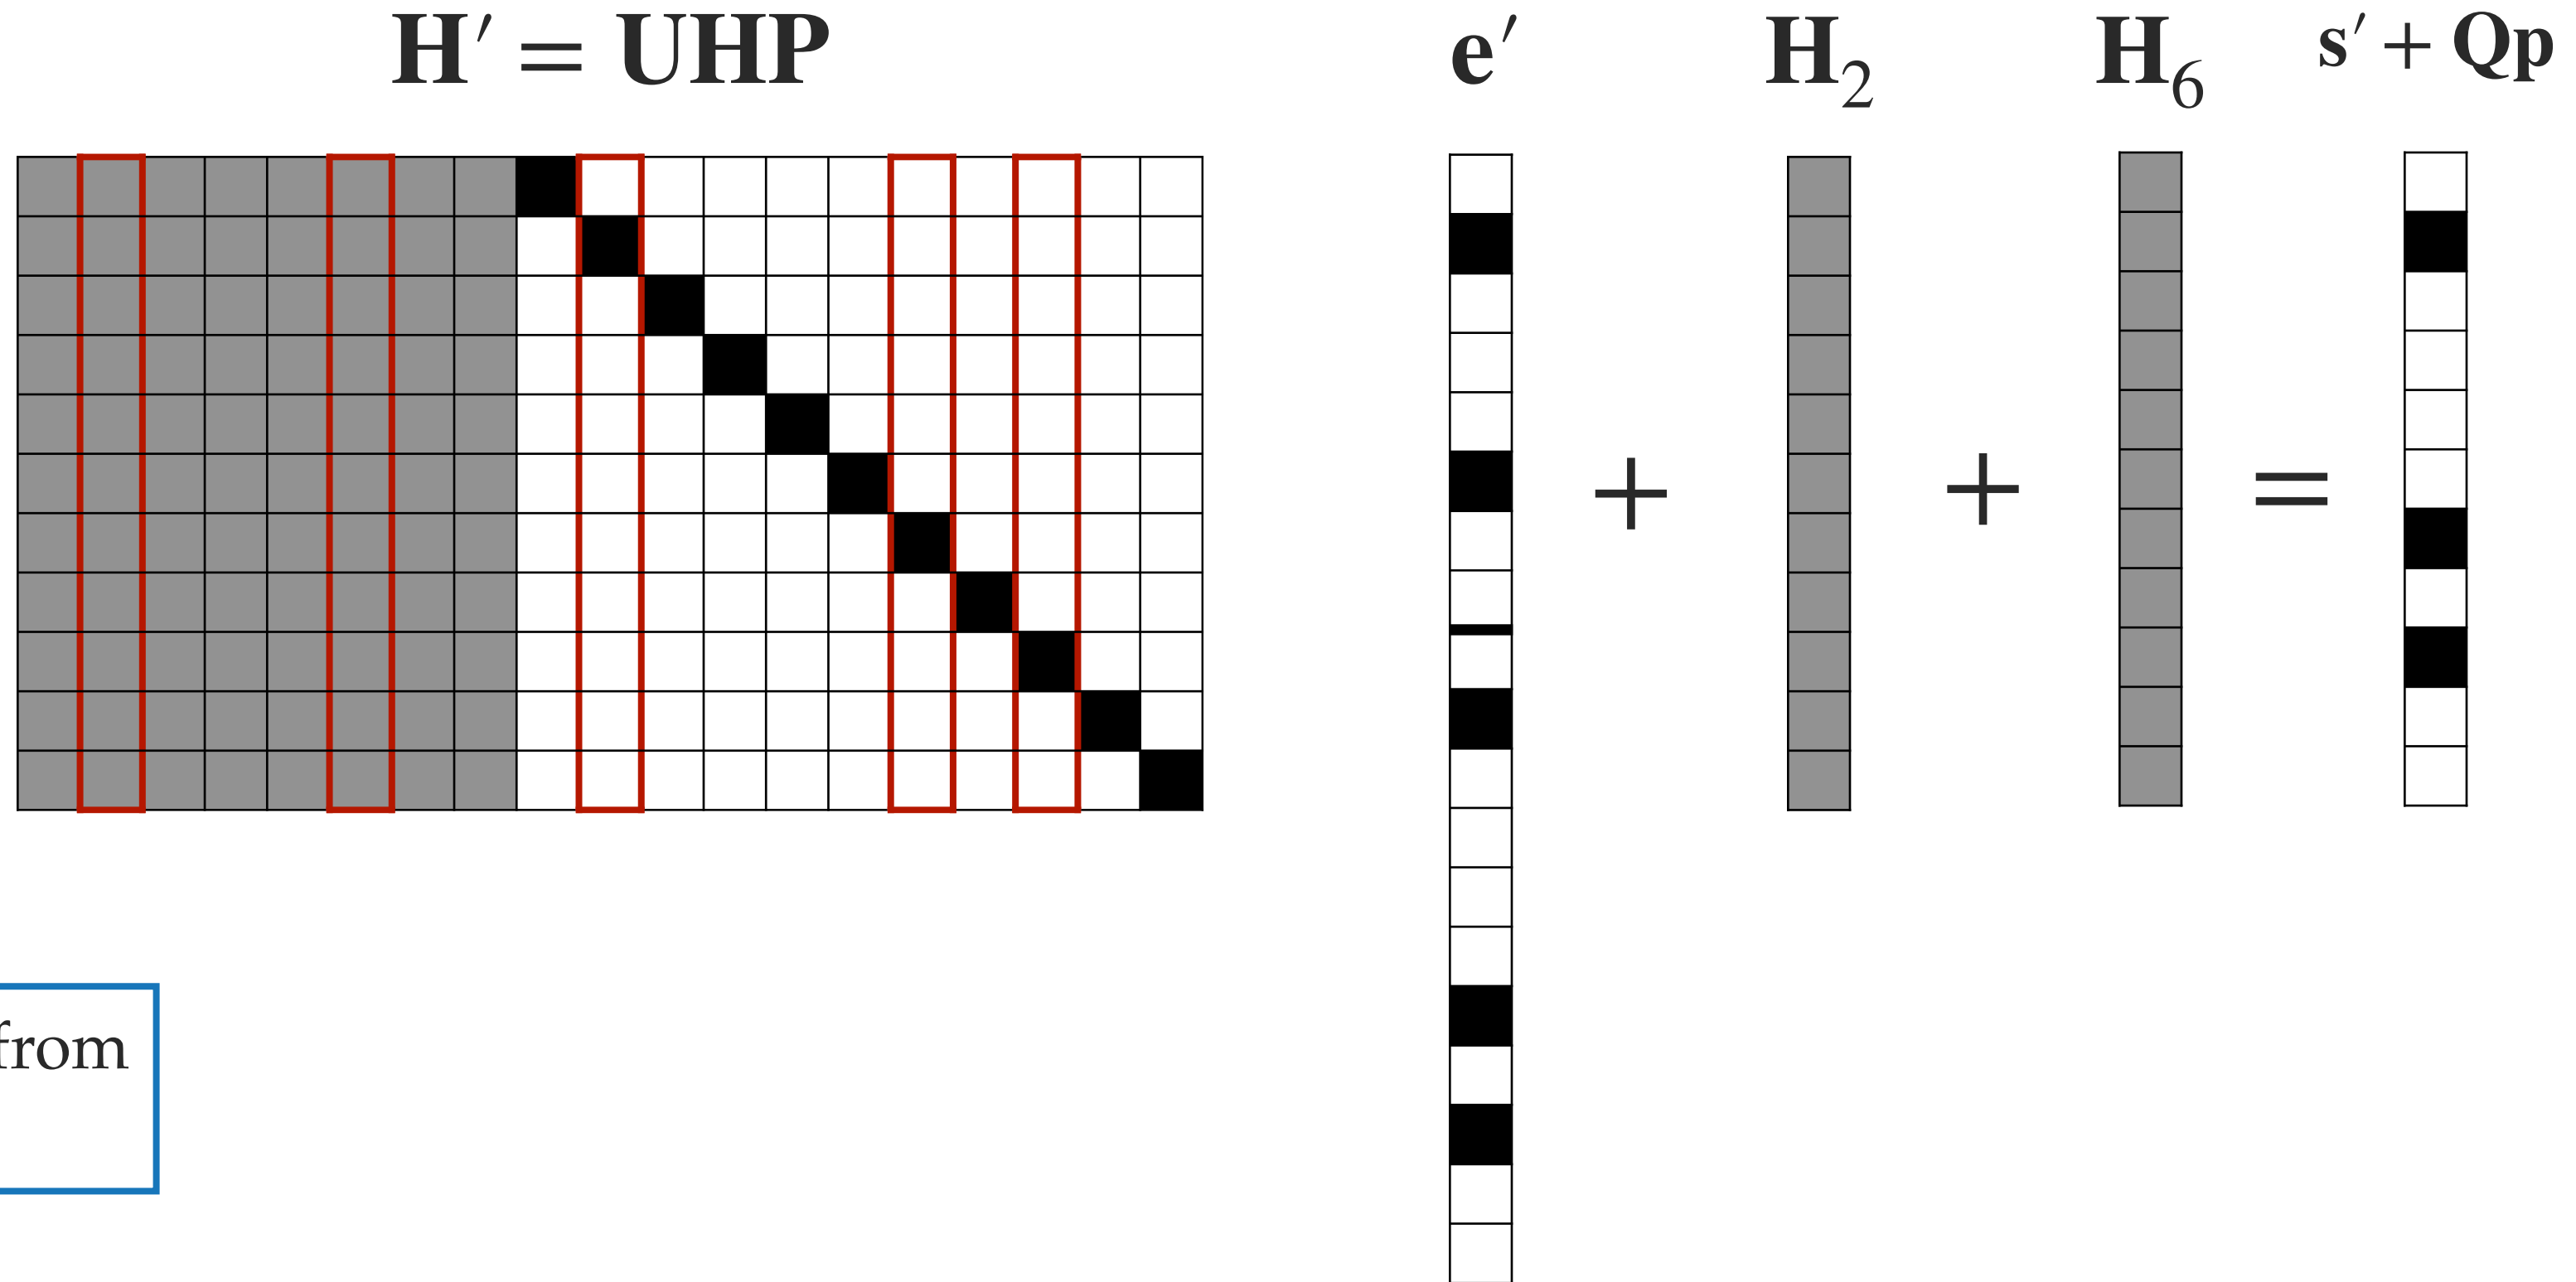

# Lee-Brickell attack

→ Permute  $\mathbf{H}$  and bring to systematic form.

Suppose that there are  $(t - p)$  errors are in the identity (right) part and  $p$  errors in the left part.

# Lee-Brickell attack

Let  $\mathbf{p}$  be a vector chosen from  $\{\mathbf{p} \in \mathbb{F}^k \mid \text{wt}(\mathbf{p}) = p\}$

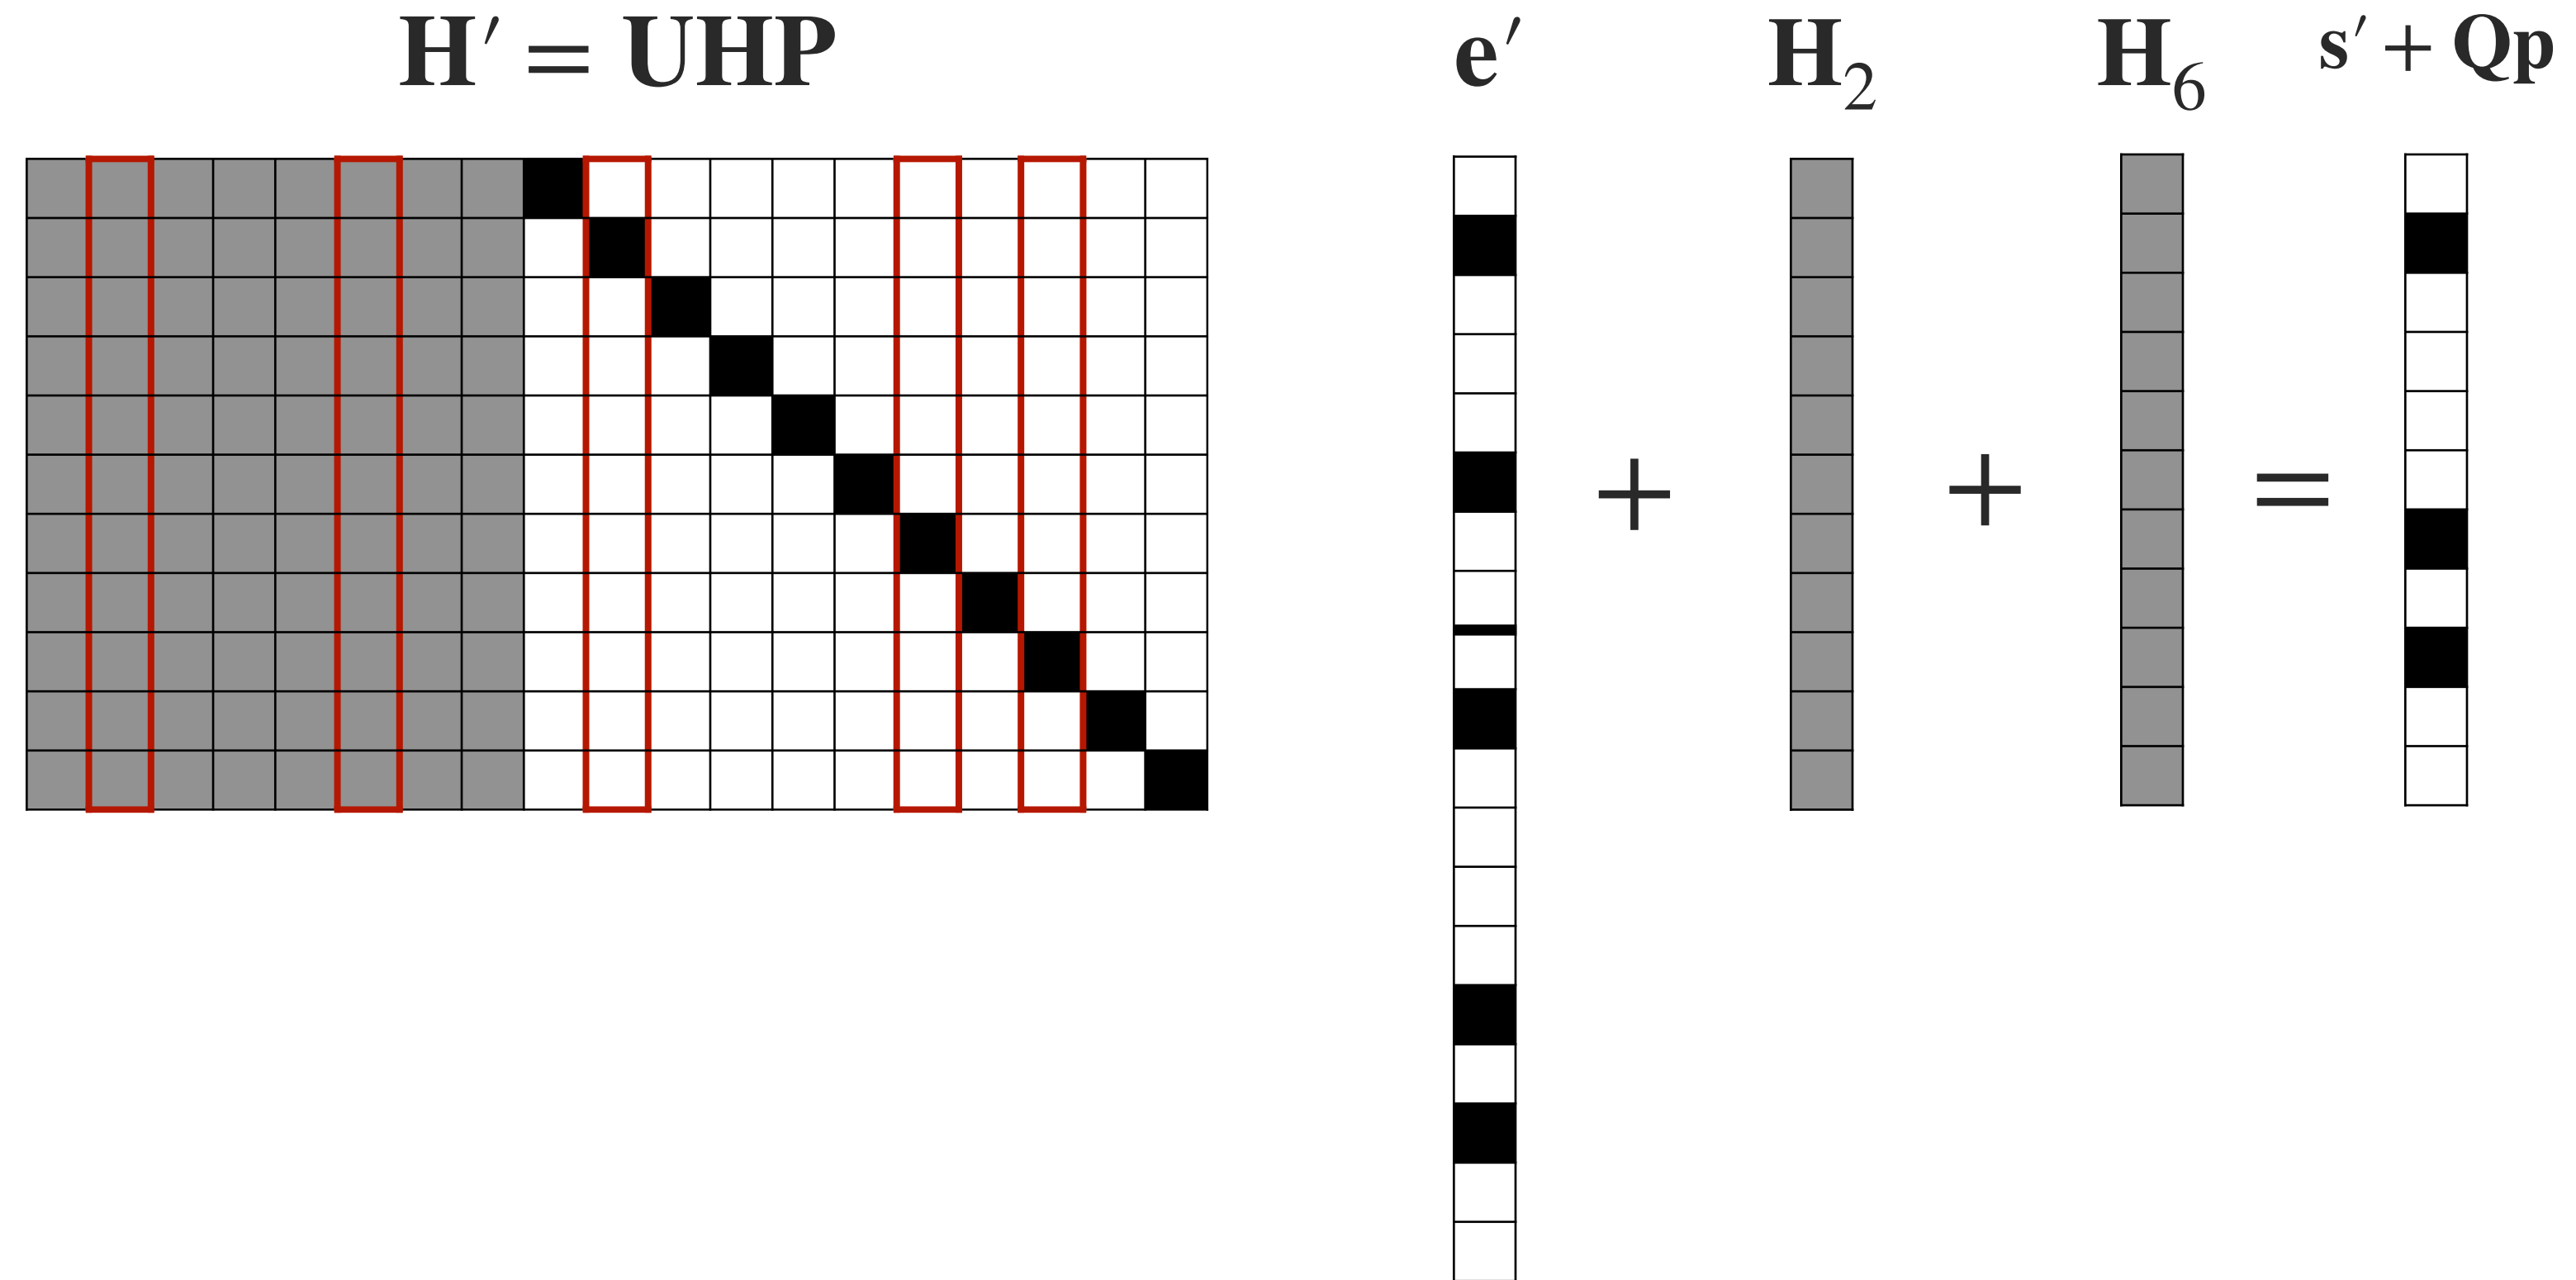

→ Permute  $\mathbf{H}$  and bring to systematic form.

Suppose that there are  $(t - p)$  errors are in the identity (right) part and  $p$  errors in the left part.

Then,  $\mathbf{s}'$  is random-looking, but  $\mathbf{s}'$  summed with the error columns on the left has weight  $t - p$ :

$$\text{wt}(\mathbf{s}' + \mathbf{Qp}) = t - p.$$

# Lee-Brickell attack

- Permute  $\mathbf{H}$  and bring to systematic form.
- Pick  $p$  of the columns on the left and compute their sum:  $\mathbf{Qp}$ .
- If  $\text{wt}(\mathbf{s}' + \mathbf{Qp}) = t - p$  then put  $\mathbf{e}' = \mathbf{p} || (\mathbf{s}' + \mathbf{Qp})$ . Output unpermuted version of  $\mathbf{e}$ .
- Else, return to the second step to choose another subset of columns from  $\mathbf{Q}$ , or return to the first step and rerandomize.

# Lee-Brickell attack: complexity

$t - p$  errors are in the identity part

$p$  errors are in the left part

Probability that we are in the correct configuration:

$$\frac{\binom{n-k}{t-p} \binom{k}{p}}{\binom{n}{t}}$$

Cost:  $\frac{\binom{n}{t}}{\binom{n-k}{t-p} \binom{k}{p}}$  matrix operations +  $\binom{k}{p}$  column additions.

# Leon's attack

Since  $s' + Qp$  should be of low weight, we check instead if an arbitrary subset of  $l$  rows are all zero.

# Leon's attack

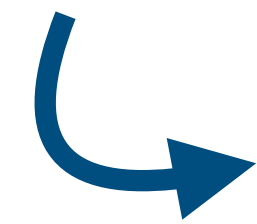

$\mathbf{H}_L$  denotes the matrix consisting of the rows of  $\mathbf{H}$  indexed by  $L$

- Pick a subset  $L$  of  $l$  rows:  $\mathbf{H}_L$ .
- Permute  $\mathbf{H}$  and bring to systematic form (then  $\mathbf{H}_L = (\mathbf{Q}_L \ \mathbf{I}_L)$ ).
- Pick  $p$  of the columns on the left and compute their sum:  $\mathbf{Q}_L \mathbf{p}$ .
- If  $\text{wt}(\mathbf{s}'_L + \mathbf{Q}_L \mathbf{p}) = 0$ 
  - If  $\text{wt}(\mathbf{s}' + \mathbf{Q} \mathbf{p}) = t - p$  then put  $\mathbf{e}' = \mathbf{p} || (\mathbf{s}' + \mathbf{Q} \mathbf{p})$ . Output unpermuted version of  $\mathbf{e}$ .
  - Else, return to the third step to choose another subset of columns from  $\mathbf{Q}$ , or return to the second step and rerandomize.
- Else, return to the third step to choose another subset of columns from  $\mathbf{Q}$ , or return to the second step and rerandomize.

# Leon's attack: complexity

 Probability that we are in the correct configuration: 
$$\frac{\binom{n-k-l}{t-p} \binom{k}{p}}{\binom{n}{t}}.$$

# Stern's attack

Suppose that there are exactly  $\frac{p}{2}$  errors in the first half of  $Q$  and exactly  $\frac{p}{2}$  errors in the first half of  $Q$ .

Instead of looking for an all zero subset of rows, we are looking for a **collision**.

# Stern's attack

- Pick a subset  $L$  of  $l$  rows:  $\mathbf{H}_L$ .
- Permute  $\mathbf{H}$  and bring to systematic form (then  $\mathbf{H}_L = (\mathbf{Q}_L \ \mathbf{I}_L)$ ).
- Split  $\mathbf{Q}$  into two disjoint parts:  $\mathbf{Q} = (\mathbf{A} \ \mathbf{B})$ .
- Build a list of vectors  $(\mathbf{s}'_L + \mathbf{A}_L \mathbf{a})$  for all (many)  $\mathbf{a}$ .
- For all (many)  $\mathbf{b}$  :
  - If  $\mathbf{B}_L \mathbf{b}$  collides with (is equal to) any of the vectors in the list built in the fourth step
    - If  $\text{wt}(\mathbf{s}' + \mathbf{Aa} + \mathbf{Bb}) = t - p$  then put  $\mathbf{e}' = \mathbf{a} || \mathbf{b} || (\mathbf{s}' + \mathbf{Aa} + \mathbf{Bb})$ . Output unpermuted version of  $\mathbf{e}$ .
  - Else return to the second step and rerandomize.

$$\mathbf{a} \text{ and } \mathbf{b} \text{ are vectors chosen from } W = \{\mathbf{w} \in \mathbb{F}_2^{k/2} \mid \text{wt}(\mathbf{w}) = \frac{p}{2}\}$$

# Stern's attack: complexity

---

Probability that we are in the correct configuration:

$$\frac{\binom{n-k-l}{t-p} \binom{k}{\frac{p}{2}}^2}{\binom{n}{t}}.$$
